

Final Report on Acute and Chronic Toxicity of Nitrate, Nitrite, Boron, Manganese, Fluoride, Chloride and Sulfate to Several Aquatic Animal Species

# Final Report on Acute and Chronic Toxicity of Nitrate, Nitrite, Boron, Manganese, Fluoride, Chloride and Sulfate to Several Aquatic Animal Species

## Prepared for:

United States Environmental Protection Agency
Office of Science and Technology
Health and Ecological Criteria Division
and
U.S. EPA, Region 5 Water Division

EPA Contract: EP-C-09-001 Work Assignments: B-12 and 1-12 Work Assignment Managers: Tom Poleck and Brian Thompson, U.S. EPA, Region 5

Prepared by:

Great Lakes Environmental Center
739 Hastings Street
Traverse City, Michigan 49686
Contacts: Jamie Saxton and Mailee Garton

### **FORWARD**

The U.S. Environmental Protection Agency is charged under the Clean Water Act (§304(a)) with periodically updating water quality criteria (WQC) to protect existing and designated uses such as aquatic life and human health. Two States in EPA Region 5 identified the need to develop criteria for which no national guidance has been developed to date. To support these State efforts, EPA Region 5 contracted (Contract EP-C-09-001, Work Assignments B-12 and 1-12) with Great Lakes Environmental Center (GLEC) and its subcontractor, the Illinois Natural History Survey (INHS), to test the acute and chronic toxic effects of nitrate, nitrite, boron, manganese, fluoride, chloride and sulfate on several aquatic animal species. The results of this Work Assignment are contained in this report.

Any comments on this document should be sent to the Work Assignment Manager, Thomas Poleck at poleck.thomas@epa.gov or

U.S. EPA Region 5 Water Quality Branch (WQ-16J) 77 W. Jackson Blvd. Chicago, IL 60604

NOTICE: This document has been reviewed in accordance with U.S. EPA policy. While every effort was made to ensure the validity of the data in this report, any State, Tribe or other party should verify for themselves that the data meets all appropriate data quality requirements. For example, rearing and testing methods for *Hyalella* have not been standardized and therefore must be evaluated as to appropriateness in any dataset used for determining WQC. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

# TABLE OF CONTENTS

Executive Summary	ix
Introduction	1
Materials and Methods	4
Chemicals Tested and Toxicology Tests Performed	10
Nitrate	
96-hr Toxicity of Nitrate on Lampsilis siliquoidea	11
96-hr Toxicity of Nitrate on Megalonaias nervosa	
48-hr Toxicity of Nitrate on <i>Chironomus dilutus</i>	
96-hr Toxicity of Nitrate on Amphinemura delosa	
96-hr Toxicity of Nitrate on <i>Sphaerium simile</i>	
96-hr Toxicity of Nitrate on <i>Hyalella azteca</i>	
96-hr Toxicity of Nitrate on <i>Pimephales promelas</i>	
32-day Toxicity of Nitrate on <i>Pimephales promelas</i>	
Nitrite	44
96-hr Toxicity of Nitrite on Lampsilis siliquoidea	45
48-hr Toxicity of Nitrite on <i>Chironomus dilutus</i>	
96-hr Toxicity of Nitrite on Amphinemura delosa	
96-hr Toxicity of Nitrite on Sphaerium simile	
96-hr Toxicity of Nitrite on <i>Hyalella azteca</i>	
96-hr Toxicity of Nitrite on <i>Pimephales promelas</i>	
32-day Toxicity of Nitrite on <i>Pimephales promelas</i>	
48-hr Toxicity of Nitrite on Ceriodaphnia dubia	
7-day Toxicity of Nitrite on Ceriodaphnia dubia	
Boron	83
96-hr Toxicity of Boron on Lampsilis siliquoidea	84
96-hr Toxicity of Boron on Megalonaias nervosa	
96-hr Toxicity of Boron on Ligumia recta	92
96-hr Toxicity of Boron on Pimephales promelas	
32-day Toxicity of Boron on <i>Pimephales promelas</i>	100
48-hr Toxicity of Boron (pH 7.75) on Ceriodaphnia dubia	
96-hr Toxicity of Boron (pH 6.75) on Pimephales promelas	110
96-hr Toxicity of Boron (pH 7.75) on Pimephales promelas	
96-hr Toxicity of Boron (pH 8.75) on Pimephales promelas	
Manganese Of he Toyloiday of Manganese on Lampilia silignoidas	125
96-ni Toxicity of Manganese on Lampsuis suiquoided.	120
96-hr Toxicity of Manganese on Megalonaias nervosa	
Fluoride	134
96-nr Toxicity of Fluoride on Sphaerium simile	133
96-hr Toxicity of Fluoride on Hyalella azteca	139
Chloride	143
96-hr Toxicity of Chloride on Musculium transversum	144
Sulfate	148
96-hr Toxicity of Sulfate on Ligumia recta	149
96-hr Toxicity of Sulfate on Megalonaias nervosa

#### **EXECUTIVE SUMMARY**

EPA guidance (EPA 1985) requires toxicity data from eight taxonomic groups, at a minimum, to derive a fully-supported water quality criterion. Two States in Region 5 are in the process of developing criteria for nitrate, boron, manganese and fluoride. This project was designed to fill existing data gaps by conducting toxicity testing on additional aquatic species for which data are absent from the literature. In addition, EPA Region 5 included several tests on nitrite, chloride and sulfate to meet other data needs and to support ongoing consultations with the U.S. Fish and Wildlife Service under the Endangered Species Act.

Specifically, the toxicity tests that were conducted are listed below along with their resultant lethal and effective concentrations.

#### A. Nitrate

1. Lampsilis siliquoidea (96-hour acute test)

$$[LC_{50} = 357 \text{ mg/L}]$$

2. Megalonaias nervosa (96-hour acute test)

$$[LC_{50} = 937 \text{ mg/L}]$$

3. Chironomus dilutus (48-hour acute test)

$$[LC_{50} = 278 \text{ mg/L}]$$

4. Amphinemura delosa (96-hour acute test)

$$[LC_{50} = 456 \text{ mg/L}]$$

5. Sphaerium simile (96-hours acute test)

$$[LC_{50} = 371 \text{ mg/L}]$$

6. Hyalella azteca (96-hour acute test)

$$[LC_{50} = 16.4 \text{ mg/L}]$$

7. Pimephales promelas (96-hour acute test)

$$[LC_{50} = 415 \text{ mg/L}]$$

8. *Pimephales promelas* (32-day chronic test)

#### B. Nitrite

9. Lampsilis siliquoidea (96-hour acute test)

$$[LC_{50} = 177 \text{ mg/L}]$$

10. Chironomus dilutus (48-hour acute test)

$$[LC_{50} = 15.6 \text{ mg/L}]$$

11. Amphinemura delosa (96-hour acute test)

$$[LC_{50} = 1.0 \text{ mg/L}]$$

12. Sphaerium simile (96-hours acute test)

$$[LC_{50} = 55.7 \text{ mg/L}]$$

13. Hyalella azteca (96-hour acute test)

$$[LC_{50} = 1.5 \text{ mg/L}]$$

14. Pimephales promelas (96-hour acute test)

$$[LC_{50} = 27.0 \text{ mg/L}]$$

15. Pimephales promelas (32-day chronic test)

16. Ceriodaphnia dubia (48-hour acute test)

$$[LC_{50} = 4.6 \text{ mg/L}]$$

17. Ceriodaphnia dubia (7-day chronic test)

#### C. Boron

18. Lampsilis siliquoidea (96-hour acute test)

$$[LC_{50} = 137 \text{ mg/L}]$$

19. Megalonaias nervosa (96-hour acute test)

$$[LC_{50} = > 544 \text{ mg/L}]$$

20. Ligumia recta (96-hour acute test)

$$[LC_{50} = 147 \text{ mg/L}]$$

21. Pimephales promelas (96-hour acute test)

$$[LC_{50} = 101 \text{ mg/L}]$$

22. Pimephales promelas (32-day chronic test)

[Survival LC<sub>50</sub> = 28.4 mg/L, LC<sub>25</sub> = 20.8 mg/L, LC<sub>20</sub> = 18.6 mg/L, LC<sub>10</sub> = 12.8 mg/L, NOEC = 12.9 mg/L, LOEC = 27.4 mg/L] [Growth EC<sub>50</sub> = 28.7 mg/L, EC<sub>25</sub> = 25.1 mg/L, EC<sub>20</sub> = 24.2 mg/L, EC<sub>10</sub> = 21.9 mg/L, NOEC = 
$$<$$
5.9 mg/L, LOEC = 5.9 mg/L]

23. Ceriodaphnia dubia (48-hour acute test at pH 7.75)

$$[LC_{50} = 76.9 \text{ mg/L}]$$

24. Pimephales promelas (96-hour acute test at pH 6.75)

$$[LC_{50} = 70.6 \text{ mg/L}]$$

25. Pimephales promelas (96-hour acute test at pH 7.75)

$$[LC_{50} = 137 \text{ mg/L}]$$

26. Pimephales promelas (96-hour acute test at pH 8.75)

$$[LC_{50} = 133 \text{ mg/L}]$$

## D. Manganese

27. Lampsilis siliquoidea (96-hour acute test)

$$[LC_{50} = 43.3 \text{ mg/L}]$$

28. Megalonaias nervosa (96-hour acute test)

$$[LC_{50} = 31.5 \text{ mg/L}]$$

## E. Fluoride

29. Sphaerium simile (96-hours acute test)

$$[LC_{50} = 62.0 \text{ mg/L}]$$

30. Hyalella azteca (96-hour acute test)

$$[LC_{50} = 13.4 \text{ mg/L}]$$

## F. Chloride

31. Musculium transversum (96-hours acute test)

$$[LC_{50} = 1,930 \text{ mg/L}]$$

## G. Sulfate

32. Ligumia recta (96-hour acute test)

$$[LC_{50} = 1,483 \text{ mg/L}]$$

33. Megalonaias nervosa (96-hour acute test)

$$[LC_{50} = 3,378 \text{ mg/L}]$$

#### INTRODUCTION

There are no federal water quality criteria for the protection of aquatic life for nitrate, nitrite, boron, manganese and fluoride. States in Region 5 of the United States Environmental Protection Agency (EPA), particularly the states of Minnesota and Illinois, are in the process of revising or developing water quality criteria for each of these parameters, with the exception of nitrite. In addition, EPA recently completed a review of the available data and undertook a draft revision of the chloride criterion.

#### **Nitrate and Nitrite**

Biological field data generated by the State of Minnesota, as well as laboratory-derived toxicity test data, suggest that nitrate at concentrations similar to those observed in the surface waters of Minnesota may cause adverse effects to aquatic life. Much of the nitrate toxicity literature focuses on the effects of nitrate, especially the effects of wastes associated with fish cultures. More recent literature reports have documented that amphibians and invertebrates appear to be more sensitive to nitrate than fish.

The state of Minnesota is evaluating the need to develop a nitrate criterion to protect aquatic life as part of its current triennial Water Quality Standards (WQS) review. Efforts by Minnesota to develop aquatic life criteria for nitrate have involved a review of all the pertinent literature to date. The primary sources were the ECOTOX database, as well as a comprehensive search of the open literature. The scientific studies were each evaluated based on methodologies in the 1985 guidance of EPA (EPA 1985), and produced two observations: 1. there is a wide variation in response among aquatic organisms to nitrate toxicity; and 2. the research has documented the toxicity of nitrate for some aquatic organisms at environmentally relevant concentrations. In addition, the literature review found seven acceptable studies that reported acute toxicity values for eleven different species. Invertebrates (especially aquatic insects) were among the most sensitive taxa. Associated chronic values from these studies were found to be acceptable for three separate species, one each for a fish, an amphibian and a cladoceran. Unfortunately, these data are insufficient to develop Tier I aquatic life criteria for nitrate. Acceptable toxicity data are lacking for two required taxonomic categories: a benthic invertebrate and one other invertebrate.

Additional nitrite acute toxicity tests are also required to complete the data set for calculating a water quality criterion consistent with EPA's 1985 guidelines. Acute tests with an amphipod (e.g., *Hyalella azteca*) and a chironomid (e.g., *Chironomus dilutus*) would best serve this purpose. In addition, completing acute and chronic (early life stage) tests with the fathead minnow (*Pimephales promelas*) would augment existing data for fish, and add an additional acute to chronic ratio for calculating a chronic criterion.

Within Region 5, field data have shown elevated levels of nitrate. Given the relationship between nitrate and nitrite, the potential for nitrite to exist in the aquatic environment under certain circumstances, the toxic effects of nitrite, and the lack of nitrite data for

most organisms other than fish, EPA wanted to assess the potential need for a nitrite criterion by generating additional nitrite toxicity data for several species of organisms.

### Boron, Manganese and Fluoride

The state of Illinois is in the process of revising its aquatic life criteria for boron, manganese and fluoride. The Illinois EPA conducted a literature review and identified the need for acute and chronic (early life stage) tests with *P. promelas* to add an additional acute to chronic ratio for calculating a chronic criterion for boron. Additionally, recent toxicity data suggest that pH affects the toxicity of boron, which is consistent with the fact that borate exists in water as a pH-dependent mixture of various borate ions. Therefore, EPA wanted to assess the effects of pH on the toxicity of boron on *Ceriodaphnia dubia* and *P. promelas*.

For fluoride, the data needs include acute and chronic tests on *Hyalella*, in order to develop an additional acute to chronic ratio with an organism other than *Pimephales* or *Daphnia*. The available acute data for an amphipod also need to be supplemented with tests conducted using a range of test water hardness levels. In order to facilitate the review of these criteria, and to provide additional support for the database, EPA also wanted to generate freshwater mussel toxicity data.

#### Chloride

EPA recently reviewed and developed additional toxicity data for chloride. As part of the review of that data and subsequent development of a draft revision of the criteria, EPA determined that additional toxicity information on resident fingernail clams (other than those from the genus *Sphaerium*) is desirable. To facilitate the acquisition of these data, EPA is interested in additional toxicity tests on other resident fingernail clams, such as *Musculium sp*.

#### Sulfate

Additional sulfate toxicity data are required to enhance EPA's basis for making a determination under the Endangered Species Act (ESA) that the recently adopted sulfate criteria by Illinois and Indiana are not likely to adversely affect threatened and endangered species. EPA Region 5 is currently consulting under Section 7 of the ESA on the Agency's approval of the Illinois and Indiana surface water quality standards. Data on the sensitivity of mussels are limited and mussels are often one of the most sensitive species to adverse water quality conditions. Therefore, EPA wanted to generate sulfate toxicity data for two mussel species (*Ligumia recta* and *Megalonaias nervosa*).

Because of the data needs outlined above, Great Lakes Environmental Center (GLEC) and its subcontractor the Illinois Natural History Survey (INHS) were contracted by the EPA to augment existing toxicity data through a series of toxicity tests. This document presents in detail the materials and methods by which GLEC and INHS performed these

toxicity tests with nitrate, nitrite, boron, manganese, fluoride, sulfate and chloride. Also included are the results of the toxicity tests, including % survival and mortality, growth and reproduction (where appropriate), water chemistry data, statistical analyses performed on the data and toxicology endpoint estimates.

## **MATERIALS AND METHODS**

GLEC and INHS performed a total of 33 acute and chronic toxicity tests (Table 1). Tests on *C. dubia, C. dilutus, H. azteca* and *P. promelas* were completed by GLEC; tests on all other species were completed by INHS. Eight of these tests were designed to determine acute and/or chronic toxicity of the chemical nitrate to seven different species of aquatic organisms; nine additional tests were designed to determine acute and/or chronic toxicity of the chemical nitrite to seven different species of aquatic organisms. Five different species of aquatic organisms were exposed to boron under acute and/or chronic conditions during nine separate toxicity tests while two aquatic organisms were exposed to manganese under acute conditions. Acute toxicity was determined for fluoride, chloride and sulfate using one of four species of mussels and *H. azteca*.

Toxicity testing under this Work Assignment was accomplished using the methods outlined in the ASTM standards (Table 2), GLEC and INHS standard operating procedures (GLEC 2009 a, GLEC 2009 b, GLEC 2009 c, GLEC 2009 d, GLEC 2009 e, GLEC 2009 f, GLEC 2009 g and INHS 2009) and the Quality Assurance Project Plan (GLEC 2009) developed for this Work Assignment. Prior to completing the toxicity test for each test chemical/organism combination, range-finding toxicity tests were initiated to determine the appropriate test chemical concentrations that would "bracket" the LC<sub>50</sub> estimates. The range of concentrations for these tests was determined either from the literature or from laboratory experiences with similar organisms. Once the appropriate range in test chemical concentrations was defined for each test chemical/organism combination, definitive toxicity testing was completed.

Dilution water used for the tests consisted of either EPA Moderately Hard Reconstituted Water (MHRW) (EPA 2002a and EPA 2002b), EPA Dilute Mineral Water (DMW) (EPA 2002 a and EPA 2002b) or de-chlorinated Lake Michigan water (City of Traverse City, Michigan water passed through an activated carbon filter). The chemical properties of the de-chlorinated Lake Michigan water are presented in Table 3; these data were generated both before and after the *P. promelas* flow-through test with boron at pH 8.75.

Water quality parameters (water temperature, pH, dissolved oxygen (DO), conductivity, hardness, alkalinity and ammonia) were measured throughout the tests at pre-determined, test-specific intervals. Water temperature, pH, DO and conductivity were measured *in situ* using calibrated meters. Hardness, alkalinity and ammonia were measured in water collected from test chambers using methods outlined in SM 2340 C (APHA *et al.* 2006 a), SM 2320 B (APHA *et al.* 2006 b) and SM 4500-NH<sub>3</sub> (APHA *et al.* 2006 c), respectively. Test concentrations of the target test chemicals were also verified using the analytical chemistry methods outlined in Table 4 and laboratory-specific standard operating procedures (GLEC 2008, GLEC 2009 h, Simmerman 2008, UL 2008 a, UL 2008 b, UL 2009 a and UL 2009 b). For toxicity testing completed by GLEC, target test chemicals were verified by the GLEC analytical chemistry laboratory (nitrate and nitrite) or SOS Analytical (boron and fluoride). Target test chemical sample analysis for toxicity testing completed by INHS was completed by the INHS analytical laboratory (nitrate and nitrite) or Underwriters Laboratories (boron, fluoride, chloride, sulfate and manganese).

Once the toxicity tests were complete, statistical analysis of the mortality (and where appropriate in chronic tests, growth or reproduction) data was completed following guidance outlined in EPA (2002 a), EPA (2002 b) and the ASTM methods (Table 2). Specifically, data were analyzed using either TOXSTAT software (Gulley 1996) or EPA's Toxicity Relationship Analysis Program (TRAP, Version 1.00). Where appropriate, data were transformed to meet the assumptions of normality and homogeneity of variance. Analysis of variance (ANOVA), parametric (e.g. Probit) or non-parametric (e.g. Spearman-Karber) tests and mathematical models (TRAP) were then used to determine appropriate toxicology endpoints, including: LC<sub>50</sub>, LC<sub>50</sub>, LC<sub>25</sub>, LC<sub>20</sub> and LC<sub>10</sub> estimates; EC<sub>50</sub>, EC<sub>25</sub>, EC<sub>20</sub>, EC<sub>10</sub> estimates for growth or reproduction; and No Observed Effects Concentration (NOEC) and Lowest Observed Effects Concentration (LOEC) estimates.

### CHEMICALS TESTED AND TOXICITY TESTS PERFORMED

#### **Nitrate**

Table 5 provides a summary of estimated  $LC_{50}$  values for the eight toxicity tests performed using nitrate.  $LC_{50}$  values ranged between 16.4 and 937 mg  $NO_3$ -N/L.

Table 5. LC<sub>50</sub> estimates for toxicity tests performed using nitrate.

Test Species and Duration	$LC_{50}$ (mg $NO_3$ -N/L)
Lampsilis siliquoidea 96 hr	357
Chironomus dilutus - 48 hr	278
Amphinemura delosa - 96 hr	456
Sphaerium simile - 96 hr	371
<i>Hyalella azteca -</i> 96 hr	16.4
Pimephales promelas - 96 hr	415
Pimephales promelas - 32 day	76.8
Megalonaias nervosa - 96 hr	937

For each of the acute toxicity tests completed using nitrate, two tables were generated: the first summarizes the test results for each toxicity test, including nominal and analytical test concentration and LC<sub>50</sub> estimates with confidence intervals; the second table summarizes analytical chemistry data collected throughout the toxicity tests. The results of chronic tests performed with nitrate were summarized in three tables: the first summarizes nominal and analytical test concentrations, LC<sub>50</sub> estimates with confidence intervals, NOEC and LOEC estimates, mean survival and mean biomass; the second table summarizes replicate-specific survival and growth data and the third table summarizes analytical chemistry data collected throughout the toxicity tests. Also discussed, if applicable, are deviations from the guidance provided in the ASTM method used to complete the toxicity testing.

Nitrate and nitrite concentration data generated by the GLEC analytical chemistry laboratory were reported as nitrate (mg NO<sub>3</sub>/L) and nitrite (mg NO<sub>2</sub>/L). For consistency (i.e. so that the data correspond to the nitrate and nitrogen data generated by the analytical chemistry laboratory used by the INHS), the GLEC data were converted to nitrate-nitrogen (N-NO<sub>3</sub>/L) and nitrite-nitrogen (N-NO<sub>2</sub>/L) for LC<sub>50</sub> determinations and reporting purposes. The data as reported by the GLEC analytical laboratory are available in the appendices.

## 96-hr Toxicity of Nitrate on Lampsilis siliquoidea

The 96-hr test to determine the toxicity of nitrate on *L. siliquoidea* was completed by INHS. Test organisms, < 5-day old juveniles collected from the Missouri State University laboratory culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 1,129, 564, 282, 141, and 70 mg N-NO<sub>3</sub>/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 6; test results are provided in Table 7. Analytical chemistry data are provided in Table 8. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 1.

## 96-hr Toxicity of Nitrate on Megalonaias nervosa

The 96-hr test to determine the toxicity of nitrate on *M. nervosa* was completed by INHS. Test organisms, < 5-day old juveniles collected from the Genoa National Fish Hatchery culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate. In one replicate of the 282 mg/L treatment, a test organism was inadvertently crushed, but this was accounted for in the LC<sub>50</sub> calculation.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 2,258, 1,129, 564, 282, and 141 mg N-NO<sub>3</sub>/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 9; test results are provided in Table 10. Analytical chemistry data are provided in Table 11. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 2.

Table 9. Test conditions for 96-hour toxicity test on *Megalonaias nervosa* with nitrate.

Summary of Toxicity Test Conditions	
Test Species and Age:	Megalonaias nervosa, juveniles <5 days old (Genoa National Fish Hatchery)

#### 48-hr Toxicity of Nitrate on Chironomus dilutus

The 48-hr test to determine the toxicity of nitrate on *C. dilutus* was completed by GLEC. Test organisms, 10-days old collected from the GLEC laboratory culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 88, 146, 244, 406, and 678 mg N-NO<sub>3</sub>/L.

Testing was conducted at  $22 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Probit method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 12; test results are provided in Table 13. Analytical chemistry data are provided in Table 14. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 3.

## 96-hr Toxicity of Nitrate on Amphinemura delosa

The 96-hr test to determine the toxicity of nitrate on *A. delosa* was completed by INHS. Test organisms, field collected nymphs, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with four organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 2,258, 1,129, 564, 282, and 141 mg N-NO<sub>3</sub>/L.

Testing was conducted at  $12 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 15; test results are provided in Table 16. Analytical chemistry data are provided in Table 17. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 4.

### 96-hr Toxicity of Nitrate on Hyalella azteca

The 96-hr test to determine the toxicity of nitrate on *H. azteca* was completed by GLEC. *H. azteca* were collected from GLEC's laboratory culture. These organisms are maintained in 10 gallon glass aquaria; plastic artificial turf and screen mesh serve as a substrate for the culture. The tanks are filled with de-chlorinated Lake Michigan water (City of Traverse City, Michigan water passed through an activated carbon filter). Cultures are fed 50 mL of 4 g/L Tetrafin slurry daily. When visible algae are not observed within the glass aquaria, algae (*Selenastrum* sp.) are used as a supplement to the Tetrafin slurry. Additionally, on occasion, dried Aspen (*Populus* sp.) leaves are prepared as a food supplement. The culture is maintained in a 16-hour light: 8-hour dark photoperiod at a temperature between 23 and 26 °C.

Test organisms were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 1.8, 2.9, 4.9, 8.1, 13.6, and 22.6 mg N-NO<sub>3</sub>/L.

Testing was conducted at  $22 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> was with the Probit (48 and 72-hour) and Trimmed Spearman-Karber (96-hour) methods.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 21; test results are provided in Table 22. Analytical chemistry data are provided in Table 23. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 6.

Table 21. Test conditions for 96-hour toxicity test on *Hyalella azteca* with nitrate.

<b>Summary of Toxicity Test Conditions</b>	
Test Species and Age:	Hyalella azteca, 10 days old, GLEC culture
2. Test Type and Duration:	Static, 96 hours
3. Test Dates:	August 6-August 10, 2009
4. Test Temperature (°C):	22 <u>+</u> 1
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s
6. Photoperiod:	16 h light, 8 h darkness
7. Feeding Regime:	None
8. Size of Test Vessel:	150 mL beaker
9. Volume of Test Solutions:	100 mL
10. No. of Test Organisms per Test Vessel:	5
11. No. of Test Vessels per Treatment:	4
12. Total No. of Test Organisms per Treatment:	20
13. Target or Nominal Test Concentrations (mg N-NO3/L):	22.6, 13.6, 8.1, 4.9, 2.9, and 1.8
Analytical Test Concentrations (average of samples collected at test initiation and termination- mg N-NO3/L):	25.8, 15.2, 9.1, 5.7, 3.2, and 2.1
15. Renewal of Test Solutions:	None
16. Dilution and Primary Control Water:	USPEA MHRW
17. Test Material:	Sodium Nitrate: Sigma Aldrich, ≥ 99.0%, ACS Reagent Cas. No. 7631-99-4, Batch # 66696LJ
18. Secondary Control Water:	None
19. Aeration:	None
20. Endpoints Measured:	Mortality (LC <sub>50</sub> )

## 96-hr Toxicity of Nitrate on Pimephales promelas

The 96-hr test to determine the toxicity of nitrate on *P. promelas* was completed by GLEC. Test organisms, collected from the GLEC laboratory culture, were acclimated to the dilution water (de-chlorinated Lake Michigan water), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); two replicates were used per treatment with ten organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 87.9, 146, 244, 407 and 678 mg N-NO<sub>3</sub>/L.

Testing was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Probit method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 24; test results are provided in Table 25. Analytical chemistry data are provided in Table 26. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 7.

## 32-day Toxicity of Nitrate on Pimephales promelas

The 32-day test to determine the toxicity of nitrate on P. promelas was completed by GLEC. The fish were continuously exposed for 32 days to five concentrations of nitrate (nominal concentrations of 28.2, 56.5, 113, 226 and 452 mg N-NO<sub>3</sub>/L) and to a dilution water control using a continuous flow-through system (Benoit et al. 1982). The temperature-controlled test concentration solutions were supplied to each test chamber via the continuous flow-through system at a rate of approximately four turnovers a day. There were four replicate test chambers for each treatment. The flow through test was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr darkness (ambient laboratory light).

After test concentrations had achieved steady state in the flow through system, the test was initiated with < 24 hour old fertilized embryos. The embryos were randomly assigned to incubation cups until each incubation cup contained 30 embryos. The incubation cups were randomly assigned to the 2.5 L glass test chambers (1 cup per chamber) and suspended in the test solutions from a rocker arm assembly. The rocker arm assembly moves the incubation cups in a reciprocal motion within each test chamber. Embryos were inspected on a daily basis and the number of live, hatched and dead embryos was recorded. On Day 5 of the test (three days after first hatch), the surviving fish were randomly thinned to achieve 20 fish in each test chamber. The remainder of the surviving fish was discarded. The number of surviving fish was recorded at test termination (32 days). In addition, the wet weights were recorded for each fish at test termination. Because of the size range of fish in each test chamber, all of the fish from each test chamber were weighed together to determine average dry weight.

There were several instances throughout the test when instantaneous water temperature measurements made within individual replicates exceeded those allowed in the toxicity testing method. However, incidences of temperature exceedance only occurred intermittingly and the average water temperatures (across the duration of the test) in each replicate were always  $\pm$  0.4 °C of the target test temperature (25 °C) in all treatments. In addition, the water temperature as recorded by the continuous temperature logger was never outside the range outlined in the method. Therefore, these water temperature exceedances likely had no effect on the results of this toxicity test.

In addition, there was an instance of low DO (4.3 mg/L) in one of the replicates at test termination. Because this incident occurred on the last day of the test and similarly low DO concentrations were never observed on any other day of the test, this low DO was an anomaly and likely had no effect on the results of this toxicity test.

Once the test was complete, the LC<sub>50</sub>, NOEC, and LOEC values were determined using the average measured concentrations with the Spearman Karber and ANOVA methods. LC<sub>25</sub>, LC<sub>20</sub>, LC<sub>10</sub>, EC<sub>50</sub>, EC<sub>25</sub>, EC<sub>20</sub> and EC<sub>10</sub> values were estimated using EPA's TRAP.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 27; test results are provided in Table 28. Survival and growth data are provided

in Table 29 and analytical chemistry data are provided in Table 30. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 8.

Table 27. Test conditions for 32-day toxicity test on *Pimephales promelas* with nitrate.

Su	mmary of Toxicity Test Conditions	
1.	Test Species and Age:	Pimephales promelas, (<24 hour fertilized embryos ), GLEC culture
2.	Test Type and Duration:	Continuous flow-through; 32 days
3.	Test Dates:	July 24-August 25, 2009
4.	Test Temperature (°C):	25 <u>+</u> 1
5.	Light Quality:	Ambient Laboratory, 10-20 μE/m²/s
6.	Photoperiod:	16 h light, 8 h darkness
7.	Feeding Regime:	Live Brine Shrimp (Artemia nauplii) Twice daily
8.	Size of Test Vessel:	2.5 Liter glass Tank
9.	Volume of Test Solutions:	2,000 mL
10.	No. of Test Organisms per Test Vessel:	30 eggs, thinned to 20 larvae after hatch
11.	No. of Test Vessels per Treatment:	4
12.	Total No. of Test Organisms per Treatment:	120 eggs, thinned to 80 larvae after hatch
13.	Target or Nominal Test Concentrations (mg $N-NO_3/L$ ):	452, 226, 113, 56.5, and 28.2
14.	Analytical Test Concentrations (average of samples collected at test initiation and termination- mg N-NO <sub>3</sub> /L):	441, 226, 109, 48.6, and 21.7
15.	Renewal of Test Solutions:	Continuous flow through, 4 turnovers per day
16.	Dilution and Primary Control Water:	De-chlorinated Lake Michigan Water
17.	Test Material:	Sodium Nitrate: Sigma Aldrich, ≥ 99.0%, ACS Reagent Cas. No. 7631-99-4, Batch # 66696LJ
18.	Secondary Control Water:	None
19.	Aeration:	None
20.	Endpoints Measured:	Survival (LC $_{50}$ , LC $_{25}$ , LC $_{20}$ and LC $_{10}$ , NOEC and LOEC) and Growth (EC $_{50}$ , EC $_{25}$ , EC $_{20}$ and EC $_{10}$ , NOEC and LOEC)

#### **Nitrite**

Table 31 provides a summary of estimated  $LC_{50}$  values for the nine toxicity tests performed using nitrite.  $LC_{50}$  values ranged between 1.0 and 177 mg NO<sub>3</sub>-N/L.

Table 31. LC<sub>50</sub> estimates for toxicity tests performed using nitrite.

Test Species and Duration	$LC_{50}$ (mg $NO_2$ -N/L)
Ceriodaphnia dubia - 48 hr	4.6
Lampsilis siliquoidea 96 hr	177
Chironomus dilutus - 48 hr	15.6
Amphinemura delosa - 96 hr	1.0
Sphaerium simile - 96 hr	55.7
<i>Hyalella azteca -</i> 96 hr	1.5
Pimephales promelas - 96 hr	27.0
Pimephales promelas - 32 day	11.3
<i>Ceriodaphnia dubia</i> - 7 day	4.7

For each of the acute toxicity tests completed using nitrite, two tables were generated: the first summarizes the test results for each toxicity test, including nominal and analytical test concentration and  $LC_{50}$  estimates with confidence intervals; the second table summarizes analytical chemistry data collected throughout the toxicity tests. The results of chronic tests performed with nitrite were summarized in three tables: the first summarizes nominal and analytical test concentrations,  $LC_{50}$  estimates with confidence intervals, NOEC and LOEC estimates, mean survival and mean biomass; the second table summarizes replicate-specific survival and growth data and the third table summarizes analytical chemistry data collected throughout the toxicity tests. Also discussed, if applicable, are deviations from the guidance provided in the ASTM method used to complete the toxicity testing.

Nitrate and nitrite concentration data generated by the GLEC analytical chemistry laboratory were reported as nitrate (mg NO $_3$ /L) and nitrite (mg NO $_2$ /L). For consistency (i.e. so that the data correspond to the nitrate and nitrogen data generated by the analytical chemistry laboratory used by the INHS), the GLEC data were converted to nitrate-nitrogen (N-NO $_3$ /L) and nitrite-nitrogen (N-NO $_2$ /L) for LC $_5$ 0 determinations and reporting purposes. The data as reported by the GLEC analytical laboratory are available in the appendices.

### 96-hr Toxicity of Nitrite on Lampsilis siliquoidea

The 96-hr test to determine the toxicity of nitrite on L. siliquoidea was completed by INHS. Test organisms, < 5-day old juveniles collected from the Missouri State University laboratory culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 304, 152, 76, 38, 19, and 9.5 mg  $N-NO_2/L$ .

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 32; test results are provided in Table 33. Analytical chemistry data are provided in Table 34. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 9.

Table 32. Test conditions for 96-hour toxicity test on *Lampsilis siliquoidea* with nitrite.

Summary of Toxicity Test Conditions	
Test Species and Age:	Lampsilis siliquoidea, juveniles <5 days old, Missouri State University
2. Test Type and Duration:	Static, 96 hours
3. Test Dates:	September 08 - 12, 2009
4. Test Temperature (°C):	20 <u>+</u> 1
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s
6. Photoperiod:	16 h light, 8 h darkness
7. Feeding Regime:	None
8. Size of Test Vessel:	50 mL beaker
9. Volume and Depth of Test Solutions:	40 mL

### 48-hr Toxicity of Nitrite on Chironomus dilutus

The 48-hr test to determine the toxicity of nitrite on *C. dilutus* was completed by GLEC. Serial dilutions. Test organisms, 10-days old from the GLEC culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 2.4, 3.9, 6.6, 11, 18 and 30 mg NO<sub>2</sub>-N/L.

Testing was conducted at  $22 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Probit method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 35; test results are provided in Table 36. Analytical chemistry data are provided in Table 37. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 10.

Table 35. Test conditions for 48-hour toxicity test on *Chironomus dilutus* with nitrite.

Summary of Toxicity Test Conditions	
Test Species and Age:	Chironomus dilutus, 10 days old, GLEC culture
2. Test Type and Duration:	Static, 48 hours
3. Test Dates:	July 23-July 25, 2009
4. Test Temperature (°C):	22 <u>+</u> 1
5. Light Quality:	Ambient Laboratory, 10-20 μE/m <sup>2</sup> /s
6. Photoperiod:	16 h light, 8 h darkness
7. Feeding Regime:	None
8. Size of Test Vessel:	150 mL beaker
9. Volume of Test Solutions:	100 mL
10. No. of Test Organisms per Test Vessel:	5
11. No. of Test Vessels per Treatment:	4
12. Total No. of Test Organisms per Treatment:	20
13. Target or Nominal Test Concentrations (mg NO <sub>2</sub> -N/L):	30, 18, 11, 6.6, 3.9, and 2.4
14. Measured Test Concentrations (average of samples collected at test initiation and termination- mg NO <sub>2</sub> - N/L):	32.4, 19, 11, 6.8, 4.0, and 2.6
15. Renewal of Test Solutions:	None
16. Dilution and Primary Control Water:	USEPA MHRW
17. Test Material:	Sodium Nitrite: Sigma Aldrich, 97 +%, ACS Reagent Cas. No. 7632-00-0, Batch # 08316DJ
18. Secondary Control Water:	None
19. Aeration:	None
20. Endpoints Measured:	Mortality (LC <sub>50</sub> )

### 96-hr Toxicity of Nitrite on Amphinemura delosa

The 96-hr test to determine the toxicity of nitrite on *A. delosa* was completed by INHS. Test organisms, field-collected nymphs, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 12, 6.1, 3.0, 1.5, and 0.8 mg N-NO<sub>2</sub>/L.

Testing was conducted at  $12 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 38; test results are provided in Table 39. Analytical chemistry data are provided in Table 40. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 11.

# 96-hr Toxicity of Nitrite on Hyalella azteca

The 96-hr test to determine the toxicity of nitrite on *H. azteca* was completed by GLEC. *H. azteca* were collected from GLEC's laboratory culture. These organisms are maintained in 10 gallon glass aquaria; plastic artificial turf and screen mesh serve as a substrate for the culture. The tanks are filled with de-chlorinated Lake Michigan water (City of Traverse City, Michigan water passed through an activated carbon filter). Cultures are fed 50 mL of 4 g/L Tetrafin slurry daily. When visible algae are not observed within the glass aquaria, algae (*Selenastrum* sp.) are used as a supplement to the Tetrafin slurry. Additionally, on occasion, dried Aspen (*Populus* sp.) leaves are prepared as a food supplement. The culture is maintained in a 16-hour light: 8-hour dark photoperiod at a temperature between 23 and 26 °C.

Test organisms were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 0.40, 0.67, 1.1, 1.8 and 3.0 mg  $NO_2$ -N/L.

Testing was conducted at  $22 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> was determined using the Probit method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 44; test results are provided in Table 45. Analytical chemistry data are provided in Table 46. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 13.

Table 44. Test conditions for 96-hour toxicity test on *Hyalella azteca* with nitrite.

<b>Summary of Toxicity Test Conditions</b>	
Test Species and Age:	Hyalella azteca, 10 days old, GLEC culture
2. Test Type and Duration:	Static, 96 hours
3. Test Dates:	August 6-August 10, 2009
4. Test Temperature (°C):	22 ± 1
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s
6. Photoperiod:	16 h light, 8 h darkness
7. Feeding Regime:	None
8. Size of Test Vessel:	150 mL beaker
9. Volume of Test Solutions:	100 mL
10. No. of Test Organisms per Test Vessel:	5
11. No. of Test Vessels per Treatment:	4
12. Total No. of Test Organisms per Treatment:	20
13. Target or Nominal Test Concentrations (mg NO <sub>2</sub> -N/L):	3.0, 1.8, 1.1, 0.67 and 0.40
<ol> <li>Analytical Test Concentrations (average of samples collected at test initiation and termination- mg NO<sub>2</sub>- N/L):</li> </ol>	4.1, 2.4, 1.4, 0.81 and 0.54
15. Renewal of Test Solutions:	None
16. Dilution and Primary Control Water:	USEPA MHRW
17. Test Material:	Sodium Nitrite: Sigma Aldrich, 97 +%, ACS Reagent Cas. No. 7632-00-0, Batch # 08316DJ
18. Secondary Control Water:	None
19. Aeration:	None
20. Endpoints Measured:	Mortality (LC <sub>50</sub> )

# 96-hr Toxicity of Nitrite on Pimephales promelas

The 96-hr test to determine the toxicity of nitrite on *P. promelas* was completed by GLEC. Test organisms, collected from the GLEC laboratory culture, were acclimated to the dilution water (de-chlorinated Lake Michigan water), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); two replicates were used per treatment with ten organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 3.9, 6.6, 11, 18 and 30 mg NO<sub>2</sub>-N/L.

Testing was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Trimmed Spearman-Karber and Probit methods.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 47; test results are provided in Table 48. Analytical chemistry data are provided in Table 49. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 14.

# 32-day Toxicity of Nitrite on Pimephales promelas

The 32-day test to determine the toxicity of nitrite on P. promelas was completed by GLEC. The fish were continuously exposed for 32 days to five concentrations of nitrite (nominal concentrations of 1.9, 3.8, 7.6, 15 and 30 mg NO<sub>2</sub>-N/L – dilution factor of 0.5) and to a dilution water control using a continuous flow-through system (Benoit et al. 1982). The temperature-controlled test concentration solutions were supplied to each test chamber via the continuous flow-through system at a rate of approximately four turnovers a day. There were four replicate test chambers for each treatment. The flow through test was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr darkness (ambient laboratory light).

After test concentrations had achieved steady state in the flow through system, the test was initiated with < 24 hour old fertilized embryos. The embryos were randomly assigned to incubation cups until each incubation cup contained 30 embryos. The incubation cups were randomly assigned to the 2.5 L glass test chambers (1 cup per chamber) and suspended in the test solutions from a rocker arm assembly. The rocker arm assembly moves the incubation cups in a reciprocal motion within each test chamber. Embryos were inspected on a daily basis and the number of live, hatched and dead embryos was recorded. On Day 5 of the test (three days after first hatch), the surviving fish were randomly thinned to achieve 20 fish in each test chamber. The remainder of the surviving fish was discarded. The number of surviving fish was recorded at test termination (32 days). In addition, the wet weights were recorded for each fish at test termination. Because of the size range of fish in each test chamber, all of the fish from each test chamber were weighed together to determine average dry weight.

Instantaneous water temperature measurements made on August 11, 2009 (Day 4) ranged from 25.5°C -26.3°C within individual replicates; this exceeded the allowed range of 25  $\pm$  1 °C in the toxicity testing method. However, the average water temperature (across the duration of the test) in each replicate was always  $\pm$  0.3 °C of the target test temperature (25 °C) in all treatments. In addition, the water temperature as recorded by the continuous temperature logger was never outside the range outlined in the method. Therefore, the water temperature exceedance likely had no effect on the results of this test.

In addition, on test day 24 there was an instance of low DO (5.8 mg/L) in replicate four of the laboratory control. Low DO concentrations were never observed on any other day of the test. Therefore, the one instance of low DO was an anomaly and likely had no effect on the results of this test.

On August 27, 2009 (day 20) a diluter malfunction (stock solution metering pump) occurred for 8 hours. Analytical chemistry samples were collected from replicate one of each test concentration subsequent to this malfunction that analysis indicated that the test solution concentrations were significantly less than the target concentrations. The measured concentration of nitrite in the five test concentrations on day 20 was less than 50 percent of the time-weighted average measured concentration; the duration of the malfunction was less than 10 percent (approximately 3.1 percent) of the total duration of

the test. Therefore, the diluter malfunction likely had little, if any, affect on the results of this test.

Once the test was complete, the LC<sub>50</sub>, NOEC and LOEC values were determined using the average measured concentrations with the Spearman Karber and ANOVA methods while LC<sub>25</sub>, LC<sub>20</sub>, LC<sub>10</sub> values were determined with the Probit method. EC<sub>50</sub>, EC<sub>25</sub>, EC<sub>20</sub> and EC<sub>10</sub> values were estimated using EPA's TRAP.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 50; test results are provided in Table 51. Survival and growth data are provided in Table 52 and analytical chemistry data are provided in Table 53. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 15.

Table 50. Test conditions for 32-day toxicity test on *Pimephales promelas* with nitrite.

Summary of Toxicity Test Conditions	
Test Species and Age:	Pimephales promelas, (<24 hour fertilized embryos), GLEC culture
2. Test Type and Duration:	Continuous flow-through; 32 days
3. Test Dates:	August 7-September 8, 2009
4. Test Temperature (°C):	25 ± 1
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s
6. Photoperiod:	16 h light, 8 h darkness
7. Feeding Regime:	Live Brine Shrimp (Artemia nauplii) Twice daily
8. Size of Test Vessel:	2.5 Liter glass Tank
9. Volume of Test Solutions:	2000 mL
10. No. of Test Organisms per Test Vessel:	30 eggs, thinned to 20 larvae after hatch
11. No. of Test Vessels per Treatment:	4
12. Total No. of Test Organisms per Treatment:	120 eggs, thinned to 80 larvae after hatch
13. Target or Nominal Test Concentrations (mg NO <sub>2</sub> -N/L):	30, 15, 7.6, 3.8, and 1.9
14. Analytical Test Concentrations (average of samples collected at test initiation and termination- mg NO <sub>2</sub> -N/L):	30, 15, 6.8, 3.4, and 1.7
15. Renewal of Test Solutions:	Continuous flow through, 4 turnovers per day
16. Dilution and Primary Control Water:	De-chlorinated Lake Michigan Water
17. Test Material:	Sodium Nitrite: Sigma Aldrich, 97 +%, ACS Reagent Cas. No. 7632-00-0, Batch # 08316DJ
18. Secondary Control Water:	None
19. Aeration:	None
20. Endpoints Measured:	Survival (LC <sub>50</sub> , LC <sub>25</sub> , LC <sub>20</sub> and LC <sub>10</sub> , NOEC and LOEC) and Growth (EC <sub>50</sub> , EC <sub>25</sub> , EC <sub>20</sub> and EC <sub>10</sub> , NOEC and LOEC)

\* August 20,2009 (day 20) a metering diluter malfunction occurred and analytical chemistry samples were collected.

### 48-hr Toxicity of Nitrite on Ceriodaphnia dubia

The 48-hr test to determine the toxicity of nitrite on *C. dubia* was completed by GLEC. Test organisms, < 24-hours old collected from the GLEC laboratory culture, were acclimated to the dilution water (DMW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 0.99, 1.6, 2.7, 4.6, and 7.6 mg NO<sub>2</sub>-N/L.

Testing was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Probit and Spearman Karber methods.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 54; test results are provided in Table 55. Analytical chemistry data are provided in Table 56. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 16.

### 7-day Toxicity of Nitrite on Ceriodaphnia dubia

The 7-day test to determine the toxicity of nitrite on *C. dubia* was completed by GLEC. Test organisms, < 24-hours old collected from the GLEC laboratory culture, were acclimated to the dilution water (DMW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); ten replicates were used per treatment with one organism per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static-renewal conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 0.48, 0.95, 1.9, 3.8, and 7.6 mg NO<sub>2</sub>-N/L.

Testing was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). On a daily basis, organisms were fed *Selenastrum* capricornutum and YTC (at renewal) and examined for mortality. As outlined in ASTM Method E1295 (ASTM 2006 b), the duration of this test is based primarily on brood production. Therefore, because greater than 60% of surviving control females had three broods at Day 6 of the test, the test was terminated early and no results were reported for Day 7.

Once the test was complete, the 48-hour and 6-day LC<sub>50</sub> values and 6-day NOEC and LOEC values were determined using the average measured concentrations with the Spearman Karber and ANOVA methods. LC<sub>25</sub>, LC<sub>20</sub> and LC<sub>10</sub> values were determined using the Probit method and EC<sub>50</sub>, EC<sub>25</sub>, EC<sub>20</sub> and EC<sub>10</sub> values were estimated using EPA's TRAP.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 57; test results are provided in Table 58. Analytical chemistry data are provided in Table 59. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 17.

Table 57. Test conditions for 7-day toxicity test on Ceriodaphnia dubia with nitrite.

Summary of Toxicity Test Conditions								
Test Species and Age:	Ceriodaphnia dubia, < 24 hours old, GLEC culture							
2. Test Type and Duration:	Three Brood Static-Renewal							
3. Test Dates:	August 21-August 27, 2009							
4. Test Temperature (°C):	25 <u>+</u> 1							
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s							
6. Photoperiod:	16 h light, 8 h darkness							
7. Feeding Regime:	Daily: Selenastrum capricornutum and YTC at renewal							
8. Size of Test Vessel:	30 mL beaker							
9. Volume Test Solutions:	15 mL							
10. No. of Test Organisms per Test Vessel:	1							
11. No. of Test Vessels per Treatment:	10							
12. Total No. of Test Organisms per Treatment:	10							
13. Target or Nominal Test Concentrations (mg NO <sub>2</sub> -N/L):	7.6, 3.8, 1.9, 0.95, and 0.48							
14. Analytical Test Concentrations (average of samples collected at test initiation and termination- mg NO <sub>2</sub> - N/L):	7.3, 3.6, 1.8, 0.82, and 0.36							
15. Renewal of Test Solutions:	Daily							
16. Dilution and Primary Control Water:	USEPA DMW							
17. Test Material:	Sodium Nitrite: Sigma Aldrich, 97 +%, ACS Reagent Cas. No. 7632-00-0, Batch # 08316DJ							
18. Secondary Control Water:	Boardman River Culture Water							
19. Aeration:	None							
20. Endpoints Measured:	Survival (LC <sub>50</sub> , LC <sub>25</sub> , LC <sub>20</sub> and LC <sub>10</sub> , NOEC and LOEC) and Reproduction (EC <sub>50</sub> , EC <sub>25</sub> , EC <sub>20</sub> and EC <sub>10</sub> , NOEC and LOEC)

New" test solutions are fresh solutions prepared each day and are used to initiate the toxicity test and to renew the existing test solutions.

#### Boron

Table 60 provides a summary of estimated  $LC_{50}$  values for the nine toxicity tests performed using boron.  $LC_{50}$  values ranged between 28.4 and >544 mg B/L.

Table 60. LC<sub>50</sub> estimates for toxicity tests performed using boron.

Test Species and Duration	LC <sub>50</sub> (mg B/L)
Lampsilis siliquoidea 96 hr	137
Pimephales promelas - 96 hr	101
Pimephales promelas - 32 day	28.4
Ceriodaphnia dubia - 48 hr (pH 7.75)	76.9
Pimephales promelas - 96 hr (pH 6.75)	70.6
Pimephales promelas - 96 hr (pH 7.75)	137
Pimephales promelas - 96 hr (pH 8.75)	133
Ligumia recta - 96 hr	147
Megalonaias nervosa - 96 hr	> 544

For each of the acute toxicity tests completed using boron, two tables were generated: the first summarizes the test results for each toxicity test, including nominal and analytical test concentration and  $LC_{50}$  estimates with confidence intervals; the second table summarizes analytical chemistry data collected throughout the toxicity tests. The results of chronic tests performed with boron were summarized in three tables: the first summarizes nominal and analytical test concentrations,  $LC_{50}$  estimates with confidence intervals, NOEC and LOEC estimates, mean survival and mean biomass; the second table summarizes replicate-specific survival and growth data and the third table summarizes analytical chemistry data collected throughout the toxicity tests. Also discussed, if applicable, are deviations from the guidance provided in the ASTM method used to complete the toxicity testing.

# 96-hr Toxicity of Boron on Lampsilis siliquoidea

The 96-hr test to determine the toxicity of boron on *L. siliquoidea* was completed by INHS. Test organisms, < 5-day old juveniles collected from the Missouri State University laboratory culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 500, 250, 125, 62.5, and 31.3 mg B/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 61; test results are provided in Table 62. Analytical chemistry data are provided in Table 63. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 18.

# 96-hr Toxicity of Boron on Megalonaias nervosa

The 96-hr test to determine the toxicity of boron on M. nervosa was completed by INHS. Test organisms, < 5-day old juveniles collected from the Genoa National Fish Hatchery, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate. In one replicate of the 250 mg/L treatment, a test organism was inadvertently crushed, but this was accounted for in the  $LC_{50}$  calculation.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 500, 250, 125, 62.5, and 31.3 mg B/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 64; test results are provided in Table 65. Analytical chemistry data are provided in Table 66. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 19.

# 96-hr Toxicity of Boron on Ligumia recta

The 96-hr test to determine the toxicity of boron on L. recta was completed by INHS. Test organisms, < 5-day old juveniles collected from the Missouri State University laboratory culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate. One replicate was mistakenly loaded with only four individuals, but this was accounted for in the  $LC_{50}$  calculation.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 500, 250, 125, 62.5, and 31.3 mg B/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 67; test results are provided in Table 68. Analytical chemistry data are provided in Table 69. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 20.

#### 96-hr Toxicity of Boron on Pimephales promelas

The 96-hr test to determine the toxicity of boron on *P. promelas* was completed by GLEC. Test organisms, collected from the GLEC laboratory culture, were acclimated to the dilution water (de-chlorinated Lake Michigan water), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); two replicates were used per treatment with ten organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 38.9, 64.8, 108, 180, 300 and 500 mg B/L.

Testing was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Probit method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 70; test results are provided in Table 71. Analytical chemistry data are provided in Table 72. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 21.

### 32-day Toxicity of Boron on Pimephales promelas

The 32-day test to determine the toxicity of boron on P. promelas was completed by GLEC. The fish were continuously exposed for 32 days to five concentrations of boron (nominal concentrations of 6.3, 12.5, 25, 50 and 100 mg B/L) and to a dilution water control using a continuous flow-through system (Benoit et al. 1982). The temperature-controlled test concentration solutions were supplied to each test chamber via the continuous flow-through system at a rate of approximately four turnovers a day. There were four replicate test chambers for each treatment. The flow through test was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr darkness (ambient laboratory light).

After test concentrations had achieved steady state in the flow through system, the test was initiated with < 24 hour old fertilized embryos. The embryos were randomly assigned to incubation cups until each incubation cup contained 30 embryos. The incubation cups were randomly assigned to the 2.5 L glass test chambers (1 cup per chamber) and suspended in the test solutions from a rocker arm assembly. The rocker arm assembly moves the incubation cups in a reciprocal motion within each test chamber. Embryos were inspected on a daily basis and the number of live, hatched and dead embryos was recorded. On Day 8 of the test (four days after first hatch), the surviving fish were randomly thinned to achieve 20 fish in each test chamber. The remainder of the surviving fish was discarded. The number of surviving fish was recorded at test termination (32 days). In addition, the wet weights were recorded for each fish at test termination. Because of the size range of fish in each test chamber, all of the fish from each test chamber were weighed together to determine average dry weight.

Instantaneous water temperature measurements made on September 12 (Day 2:  $23.5^{\circ}$ C-24.5°C), October 1 (Day 21:  $23.7^{\circ}$ C-24.3°C), October 9 (Day 29:  $25.9^{\circ}$ C-26.5°C), October 11 (Day 31:  $23.7^{\circ}$ C-24.1°C), and October 12 (Day 32:  $23.8^{\circ}$ C-24.5°C) exceeded the allowable range of  $25 \pm 1$  °C in the toxicity testing method. However, the overall average water temperatures (across the duration of the test) in each replicate were within  $\pm 0.5$  °C of the target test temperature (25 °C) in all treatments. Therefore, the water temperature exceedances noted above likely had no effect on the results of this study.

On September 19 and 20, 2009 (test days 9 and 10) 60-90 percent mortality occurred in replicates one and two of the laboratory control. It is of GLEC's opinion that the equipment used during the thinning procedure on test day 8 contributed toxicity to these two control replicates, resulting in the high fish mortality. This high mortality was communicated to the EPA Work Assignment Manager and GLEC was advised to continue the test with the assumption that further control mortality would result in test failure. No further toxicity was observed in the remaining control fish throughout the test. However, because of the mortality observed in the control treatments, only replicates three and four of the laboratory control were used in the survival and growth statistical comparisons.

Once the test was complete, the  $LC_{50}$ , NOEC and LOEC values were determined using the average measured concentrations with the Spearman Karber and ANOVA methods.  $LC_{25}$ ,  $LC_{20}$  and  $LC_{10}$  values were determined using the Probit method and  $EC_{50}$ ,  $EC_{25}$ ,  $EC_{20}$  and  $EC_{10}$  values were estimated using EPA's TRAP.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 73; test results are provided in Table 74. Survival and growth data are provided in Table 75 and analytical chemistry data are provided in Table 76. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 22.

Test Species and Age:	Pimephales promelas, (<24 hour fertilized embryos ), GLEC Culture
2. Test Type and Duration:	Continuous flow-through; 32 days
3. Test Dates:	September 10-October 12, 2009
4. Test Temperature (°C):	25 ± 1
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s
6. Photoperiod:	16 h light, 8 h darkness
7. Feeding Regime:	Live Brine Shrimp (Artemia nauplii ) Twice daily
8. Size of Test Vessel:	2.5 Liter glass Tank
9. Volume of Test Solutions:	2000 mL
10. No. of Test Organisms per Test Vessel:	30 eggs, thinned to 20 larvae after hatch
11. No. of Test Vessels per Treatment:	4
12. Total No. of Test Organisms per Treatment:	120 eggs, thinned to 80 larvae after hatch
13. Target or Nominal Test Concentrations (mg/L):	100, 50.0, 25.0, 12.5 and 6.25 mg/L-boron
Analytical Test Concentrations (average of samples collected at test initiation and termination-mg/L):	112, 56.5, 27.4, 12.9, and 5.90 mg/L-nitrate
15. Renewal of Test Solutions:	Continuous flow through, 4 turnovers per day
16. Dilution and Primary Control Water:	De-Chlorinated Lake Michigan Water
17. Test Material:	Boric Acid: Sigma Aldrich, ACS Reagent >= 99.5% Cas. No. 10043-35-3, Batch 118K0007 and Borax (sodium tetraborate decahydrate) Sigma Aldrich, ≥ 99.5%, ACS reagent, Cas. No. 1303-96-4, Lot # 118K0172
18. Secondary Control Water:	None
19. Aeration:	None
20. Endpoints Measured:	Survival (LC <sub>50</sub> , LC <sub>25</sub> , LC <sub>20</sub> and LC <sub>10</sub> , NOEC and LOEC) and Growth (EC <sub>50</sub> , EC <sub>25</sub> , EC <sub>20</sub> and EC <sub>10</sub> , NOEC and LOEC)

# 48-hr Toxicity of Boron (pH 7.75) on Ceriodaphnia dubia

The 48-hr test to determine the toxicity of boron (pH 7.75) on *C. dubia* was completed by GLEC. The *C. dubia* were continuously exposed for 48-hours to five concentrations of boron and to a dilution water control with a target test pH of 7.75 (range of 7.65 to 7.85) using a continuous flow-through system (modified Benoit mini-dilutor) and an in-line pH adjustment/metering unit. The pH of both the dilution water and stock solution were adjusted by using a 1:1 ratio of sulfuric acid and hydrochloric acid (acid solution). The pH adjusted stock solution was delivered to mixing cells and diluted with pH adjusted, de-chlorinated Lake Michigan water to achieve target nominal concentrations of boron and a target test pH of 7.75.

Due to the buffering capacity of the borax and boric acid solution used to prepare the boron concentrations, EPA agreed that GLEC should target the dilution water control pH at 7.75 (range of 7.65 to 7.85). The five test concentrations were targeted to a pH of  $\pm$  0.1 pH unit from the pH value defined at test initiation in each test concentration (i.e. regardless of whether or not the pH in the test concentrations were  $\pm$  0.1 pH units from that observed in the control water). The temperature-controlled test concentration solutions were supplied to each test chamber via the continuous flow-through system at a rate of approximately four turnovers a day. There were four replicate test chambers for each treatment. The flow through test was conducted at 25  $\pm$  1 °C with a photoperiod of 16 hr light and 8 hr darkness (ambient laboratory light).

After test concentrations had achieved steady state in the flow through system, the test was initiated with < 24 hour old *C. dubia* collected from the GLEC laboratory culture. Although these organisms were cultured in, and acclimated to, the dilution water's "natural" pH (typically between a pH of 7.9 and 8.2), they were not acclimated to the pH-adjusted dilution water prior to test initiation for two reasons: 1) GLEC does not maintain a laboratory culture of *C. dubia* in de-chlorinated Lake Michigan water maintained at a pH of 7.75 and 2) adequate acclimation of the organisms to the pH-adjusted dilution water would have jeopardized the age requirement (< 24 hour old at test initiation) for test organisms required under the toxicity testing method (ASTM 2007).

The *C. dubia* were randomly assigned to test cups until each test cup contained five *C. dubia*. The test cups were randomly assigned to the 2.5 L glass test chambers (1 cup per chamber) and suspended in the test solutions from a rod. *C. dubia* were counted on a daily basis and the number of live *C. dubia* was recorded. pH was recorded twice a day, at a minimum of eight hours apart (i.e. morning and evening). The number of surviving *C. dubia* was recorded at test termination (48-hours).

The test was completed at the following nominal boron concentrations: 25.0, 50.0, 100, 200, and 400 mg/L. The average pH for the dilution water control measured in the *C. dubia* toxicity test for the 48-hour test period was 7.77. The average pH over the 48-hour test duration for the five test concentrations of 27.6, 49.8, 118, 223, and 391 mg/L was 7.92, 8.03, 8.03, 8.07, and 8.06, respectively.

Once the test was complete, the  $LC_{50}$  was determined using the average measured test concentrations with the Probit method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 77; test results are provided in Table 78. Analytical chemistry data are provided in Table 79. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 23.

Table 77. Test conditions for 48-hour toxicity test on *Ceriodaphnia dubia* with boron (pH 7.75).

# 96-hour Toxicity of Boron (pH 6.75) on Pimephales promelas

The 96-hr test to determine the toxicity of boron (pH 6.75) on *P. promelas* was completed by GLEC. The *P. promelas* (collected from the GLEC laboratory culture) were continuously exposed for 96-hours to five concentrations of boron and to a dilution water control with a target test pH of 6.75 (range of 6.65 to 6.85) using a continuous flow-through system (modified Benoit mini-dilutor) and an in-line pH adjustment/ metering unit. The pH of both the dilution water and stock solution were adjusted by using a 1:1 ratio sulfuric acid and hydrochloric acid (acid solution). The pH adjusted stock solution was delivered to mixing cells and diluted with pH adjusted Lake Michigan water to achieve target nominal concentrations of boron and a target test pH of 6.75. Due to the buffering capacity of the borax and boric acid solution used to prepare the boron concentrations, EPA agreed that GLEC should target to a pH of  $\pm$  0.1 pH unit from the pH value defined at test initiation in each test concentration (i.e. regardless of whether or not the pH in the test concentrations were  $\pm 0.1$  pH unit from that observed in the control water). The temperature-controlled test concentration solutions were supplied to each test chamber via the continuous flow-through system at a rate of approximately four turnovers a day. There were two replicate test chambers for each treatment. The flow through test was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr darkness (ambient laboratory light).

After test concentrations had achieved steady state in the flow through system, the test was initiated with the *P. promelas*. Although these organisms were cultured in, and acclimated to, the dilution water's "natural" pH (typically between a pH of 7.9 and 8.2), they were not acclimated to the pH-adjusted dilution water prior to test initiation for two reasons: 1) GLEC does not maintain a laboratory culture of *P. promelas* in dechlorinated Lake Michigan water maintained at a pH of 6.75 and 2) adequate acclimation of the organisms to the pH-adjusted dilution water may have jeopardized the weight requirement (0.1–5 g at test initiation) for test organisms required under the toxicity testing method (ASTM 2007).

The *P. promelas* were randomly assigned to the 2.5 L glass test chambers until each test chamber contained ten *P. promelas*. *P. promelas* were counted on a daily basis and the number of live *P. promelas* was recorded. pH was recorded twice a day, at a minimum of eight hours apart (i.e., morning and evening). The number of surviving *P. promelas* was recorded at test termination (96-hours).

The test was completed at the following nominal boron concentrations: 25.0, 50.0, 100, 200, and 400 mg/L (dilution factor of 0.5). The average pH for the dilution water control measured in the *P. promelas* toxicity test for the 96-hour test period was 6.67. The average pH over the 96-hour test duration for the five test concentrations of 32.9, 55.2, 122, 224, and 394 mg/L was 6.85, 6.93, 7.18, 7.28, and 7.33, respectively.

The hourly water temperatures as recorded by the continuous temperature logger did show that test temperatures fell outside the temperature allowance in the early morning on October 29, 2009 (readings of 23.8 and 23.9 °C). However, instantaneous water

temperatures measured by GLEC technicians on October 28 and later in the morning on October 29 never fell outside the acceptable range as outlined in the method. Therefore, these water temperature exceedances were very brief and likely had no effect on the results of this study.

Once the test was complete, the  $LC_{50}$  was determined using the average measured test concentrations with the Probit and Spearman method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 80; test results are provided in Table 81. Analytical chemistry data are provided in Table 82. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 24.

### 96-hr Toxicity of Boron (pH 7.75) on Pimephales promelas

The 96-hr test to determine the toxicity of boron (pH 7.75) on *P. promelas* was completed by GLEC. The *P. promelas* (collected from the GLEC laboratory culture) were continuously exposed for 96-hours to five concentrations of boron and to a dilution water control with a target test pH of 7.75 (range of 7.65 to 7.85) using a continuous flow-through system (modified Benoit mini-dilutor) and an in-line pH adjustment/metering unit. The pH of both the dilution water and stock solution were adjusted by using a 1:1 ratio of sulfuric acid and hydrochloric acid (acid solution). The pH adjusted stock solution was delivered to mixing cells and diluted with pH adjusted Lake Michigan water to achieve target nominal concentrations of boron and a target test pH of 7.75. Due to the buffering capacity of the borax and boric acid solution used to prepare the boron concentrations, EPA agreed that GLEC should target the dilution water control pH at 7.75 (range of 7.65 to 7.85). The five test concentrations were targeted to a pH of  $\pm$  0.1 pH unit from the pH value defined at test initiation in each test concentration (i.e. regardless of whether or not the pH in the test concentrations were  $\pm$  0.1 pH unit from that observed in the control water). The temperature-controlled test concentration solutions were supplied to each test chamber via the continuous flow-through system at a rate of approximately four turnovers a day. There were two replicate test chambers for each treatment. The flow through test was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr darkness (ambient laboratory light).

After test concentrations had achieved steady state in the flow through system, the test was initiated with the *P. promelas*. Although these organisms were cultured in, and acclimated to, the dilution water's "natural" pH (typically between a pH of 7.9 and 8.2), they were not acclimated to the pH-adjusted dilution water prior to test initiation for two reasons: 1) GLEC does not maintain a laboratory culture of *P. promelas* in dechlorinated Lake Michigan water maintained at a pH of 7.75 and 2) adequate acclimation of the organisms to the pH-adjusted dilution water may have jeopardized the weight requirement (0.1–5 g at test initiation) for test organisms required under the toxicity testing method (ASTM 2007).

The *P. promelas* were randomly assigned to the 2.5 L glass test chambers until each test chamber contained ten *P. promelas*. *P. promelas* were counted on a daily basis and the number of live *P. promelas* was recorded. pH was recorded twice a day, at a minimum of eight hours apart (i.e. morning and evening). The number of surviving *P. promelas* was recorded at test termination (96-hours).

The test was completed at the following nominal boron concentrations: 25.0, 50.0, 100, 200, and 400 mg/L (dilution factor of 0.5). The average pH for the dilution water control measured in the *P. promelas* toxicity test for the 96-hour test period was 7.68. The average pH over the 96-hour test duration for the five test concentrations of 28.6, 50.9, 121, 223, and 392 mg/L was 7.88, 7.98, 8.05, 8.07, and 8.06, respectively.

Once the test was complete, the  $LC_{50}$  was determined using the average measured test concentrations with the Spearman method.

### 96-hr Toxicity of Boron (pH 8.75) on Pimephales promelas

The 96-hr test to determine the toxicity of boron (pH 8.75) on P. promelas was completed by GLEC. The P. promelas (collected from the GLEC laboratory culture) were continuously exposed for 96-hours to five concentrations of boron and to a dilution water control with a target test pH of 8.75 (range of 8.65 to 8.85) using a continuous flow-through system (modified Benoit mini-dilutor) and an in-line pH adjustment/metering unit. The stock solutions used for the test were prepared by diluting a known weight (grams) of borax and boric acid to a known volume of dilution water (dechlorinated Lake Michigan water). The pH of both the dilution water and stock solution were adjusted by using sodium hydroxide. The pH adjusted stock solution was delivered to mixing cells and diluted with pH adjusted Lake Michigan water to achieve target nominal concentrations of boron and a target test pH of 8.75. The temperature-controlled test concentration solutions were supplied to each test chamber via the continuous flow-through system at a rate of approximately four turnovers a day. There were two replicate test chambers for each treatment. The flow through test was conducted at  $25 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr darkness (ambient laboratory light).

After test concentrations had achieved steady state in the flow through system, the test was initiated with the *P. promelas*. Although these organisms were cultured in, and acclimated to, the dilution water's "natural" pH (typically between a pH of 7.9 and 8.2), they were not acclimated to the pH-adjusted dilution water prior to test initiation for two reasons: 1) GLEC does not maintain a laboratory culture of *P. promelas* in dechlorinated Lake Michigan water maintained at a pH of 8.75 and 2) adequate acclimation of the organisms to the pH-adjusted dilution water may have jeopardized the weight requirement (0.1–5 g at test initiation) for test organisms required under the toxicity testing method (ASTM 2007).

The *P. promelas* were randomly assigned to the 2.5 L glass test chambers until each test chamber contained ten *P. promelas*. *P. promelas* were counted on a daily basis and the number of live *P. promelas* was recorded. pH was recorded twice a day, at a minimum of eight hours apart (i.e., morning and evening). The number of surviving *P. promelas* was recorded at test termination (96-hours).

The test was completed at the following nominal boron concentrations: 25.0, 50.0, 100, 200, and 400 mg/L (dilution factor of 0.5). The average pH for the dilution water control measured in the *P. promelas* toxicity test for the 96-hour test period was 8.75. The average pH over the 96-hour test duration for the five test concentrations of 21.1, 42.4, 112, 219, and 376 mg/L was 8.72, 8.70, 8.70, 8.70, and 8.67, respectively.

Instantaneous water temperature measurements made on February 13, 14, 15 and 16 (Days 1-4: 23.6°C-24.7°C) exceeded the allowable range of  $25 \pm 1$  °C outlined in the toxicity testing method. However, the average water temperatures across the duration of the test in each replicate were always  $\pm 0.9$  °C of the target test temperature (25 °C) in all treatments. In addition, the water temperature as recorded by the continuous temperature logger did show that the test temperature fell outside the temperature allowance during

the times of 0430 to 0830 on those days. However, due to the relatively small number of temperature readings measured outside the range, these water temperature exceedances likely had little effect on the results of this study.

Once the test was complete, the LC<sub>50</sub> was determined using the average measured test concentrations with the Probit method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 86; test results are provided in Table 87. Analytical chemistry data are provided in Table 88. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 26.

Table 86. Test conditions for 96-hour toxicity test on Pimephales promelas with

# boron (pH 8.75).

<b>Summary of Toxicity Test Conditions</b>	
Test Species and Age:	Pimephales promelas, (weight 0.13g and 22.8 mm length), GLEC Culture
2. Test Type and Duration:	Continuous flow-through, 96 hours
3. Test Dates:	February 12-February 16, 2010
4. Test Temperature (°C):	25 <u>+</u> 1
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s
6. Photoperiod:	16 h light, 8 h darkness
7. Feeding Regime:	None
8. Size of Test Vessel:	2.5 Liter glass Tank
9. Volume of Test Solutions:	2000 mL
10. No. of Test Organisms per Test Vessel:	10
11. No. of Test Vessels per Treatment:	2
12. Total No. of Test Organisms per Treatment:	20
13. Target or Nominal Test Concentrations (mg/L):	400, 200, 100, 50.0, and 25.0
Analytical Test Concentrations (average of samples collected at test initiation and termination-mg/L):	376, 219, 112, 42.4, and 21.1
15. Renewal of Test Solutions:	Continuous florestarreds Atomics and dec
16. Dilution and Primary Control Water:	Continuous flow through, 4 turnovers per day  De-chlorinated Lake Michigan Water
17. Test Material:	Boric Acid: Sigma Aldrich, ACS Reagent >= 99.5% Cas.
	No. 10043-35-3, Batch 118K0007 and Borax (sodium tetraborate decahydrate) Sigma Aldrich, ≥ 99.5%, ACS reagent, Cas. No. 1303-96-4, Lot # 118K0172
18. Secondary Control Water:	None
19. Aeration:	None
20. Endpoints Measured:	Mortality (LC <sub>50</sub> )

# Manganese

Table 89 provides a summary of estimated  $LC_{50}$  values for the two toxicity tests performed using manganese.  $LC_{50}$  values ranged between 31.5 and 43.3 mg Mn/L.

Table 89. LC<sub>50</sub> estimates for toxicity tests performed using manganese.

Test Species and Duration	LC <sub>50</sub> (mg Mn/L)
Lampsilis siliquoidea 96 hr	43.3
Megalonaias nervosa - 96 hr	31.5

For each of the acute toxicity tests completed using manganese, two tables were generated: the first summarizes the test results for each toxicity test, including nominal and analytical test concentration and  $LC_{50}$  estimates with confidence intervals; the second table summarizes analytical chemistry data collected throughout the toxicity tests. Also discussed, if applicable, are deviations from the guidance provided in the ASTM method used to complete the toxicity testing.

### 96-hr Toxicity of Manganese on Lampsilis siliquoidea

The 96-hr test to determine the toxicity of manganese on L. siliquoidea was completed by INHS. Test organisms, < 5-day old juveniles collected from the Missouri State University laboratory culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate. One replicate was mistakenly loaded with only 4 individuals, but this was accounted for in the  $LC_{50}$  calculation.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 150, 75, 37, 18.8, 9.4, and 4.7 mg Mn/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 90; test results are provided in Table 91. Analytical chemistry data are provided in Table 92. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 27.

Table 90. Test conditions for 96-hour toxicity test on *Lampsilis siliquoidea* with manganese.

Summary of Toxicity Test Conditions

### 96-hr Toxicity of Manganese on Megalonaias nervosa

The 96-hr test to determine the toxicity of manganese on M. nervosa was completed by INHS. Test organisms, < 5-day old juveniles collected from the Genoa National Fish Hatchery, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate. In one replicate of the control a test organism was inadvertently crushed, but this was accounted for in the  $LC_{50}$  calculation.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 300, 150, 75, 37.5, and 18.8 mg Mn/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 93; test results are provided in Table 94. Analytical chemistry data are provided in Table 95. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 28.

Table 93. Test conditions for 96-hour toxicity test on *Megalonaias nervosa* with manganese.

Summary of Toxicity Test Conditions							
Test Species and Age:	Megalonaias nervosa, juveniles <5 days old (Genoa National Fish Hatchery)						
2. Test Type and Duration:	Static, 96 hours						
3. Test Dates:	October 23 - 27, 2009						
4. Test Temperature (°C):	20 <u>+</u> 1						
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s						
6. Photoperiod:	16 h light, 8 h darkness						
7. Feeding Regime:	None						
8. Size of Test Vessel:	50 mL beaker						
9. Volume of Test Solutions:	40 mL						
10. No. of Test Organisms per Test Vessel:	5						
11. No. of Test Vessels per Treatment:	4						
12. Total No. of Test Organisms per Treatment:	20						
13. Test Concentrations (mg Mn/L):	300, 150, 75, 37.5, and 18.8

#### Fluoride

Table 96 provides a summary of estimated  $LC_{50}$  values for the two toxicity tests performed using fluoride.  $LC_{50}$  values ranged between 13.4 and 62.0 mg F/L.

Table 96. LC<sub>50</sub> estimates for toxicity tests performed using fluoride.

Test Species and Duration	LC <sub>50</sub> (mg F/L)
Sphaerium simile - 96 hr	62.0
<i>Hyalella azteca</i> - 96 hr	13.4

For each of the acute toxicity tests completed using fluoride, two tables were generated: the first summarizes the test results for each toxicity test, including nominal and analytical test concentration and  $LC_{50}$  estimates with confidence intervals; the second table summarizes analytical chemistry data collected throughout the toxicity tests.

#### 96-hr Toxicity of Fluoride on Sphaerium simile

The 96-hr test to determine the toxicity of fluoride on *S. simile* was completed by INHS. Test organisms, juveniles released from field collected adults, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 800, 400, 200, 100, and 50 mg F/L.

Testing was conducted at  $22 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 97; test results are provided in Table 98. Analytical chemistry data are provided in Table 99. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 29.

### 96-hr Toxicity of Fluoride on Hyalella azteca

The 96-hr test to determine the toxicity of fluoride on *H. azteca* was completed by GLEC. *H. azteca* were collected from GLEC's laboratory culture. These organisms are maintained in 10 gallon glass aquaria; plastic artificial turf and screen mesh serve as a substrate for the culture. The tanks are filled with de-chlorinated Lake Michigan water (City of Traverse City, Michigan water passed through an activated carbon filter). Cultures are fed 50 mL of 4 g/L Tetrafin slurry daily. When visible algae are not observed within the glass aquaria, algae (*Selenastrum* sp.) are used as a supplement to the Tetrafin slurry. Additionally, on occasion, dried Aspen (*Populus* sp.) leaves are prepared as a food supplement. The culture is maintained in a 16-hour light: 8-hour dark photoperiod at a temperature between 23 and 26 °C.

Test organisms were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 7.8, 12.9, 21.6, 36.0, 60.0, and 100 mg F/L.

Testing was conducted at  $22 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Probit and Spearman Karber methods.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 100; test results are provided in Table 101. Analytical chemistry data are provided in Table 102. Accompanying information, including raw laboratory data, analytical chemistry data, reference toxicant data and statistical analyses, is provided in Appendix 30.

## Chloride

Table 103 provides a summary of the estimated  $LC_{50}$  value for the toxicity test performed using chloride.

Table 103.  $LC_{50}$  estimate for toxicity test performed using chloride.

<b>Test Species and Duration</b>	LC <sub>50</sub> (mg Cl/L)
<i>Musculium transversum</i> - 96 hr	1,930

For the acute toxicity test completed using chloride, two tables were generated: the first summarizes the test results for the toxicity test, including nominal and analytical test concentration and  $LC_{50}$  estimates with confidence intervals; the second table summarizes analytical chemistry data collected throughout the toxicity test.

### 96-hr Toxicity of Chloride on Musculium transversum

The 96-hr test to determine the toxicity of chloride on *M. transversum* was completed by INHS. Test organisms, juveniles released from field collected adults, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 8,000, 4,018, 2,028, 1,032, and 535 mg Cl/L.

Testing was conducted at  $22 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 104; test results are provided in Table 105. Analytical chemistry data are provided in Table 106. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 31.

Table 104. Test conditions for 96-hour toxicity test on *Musculium transversum* with chloride.

Summary of Toxicity Test Conditions							
Test Species and Age:	Musculium transversum, juveniles (released from field-collected adults)						
2. Test Type and Duration:	Static, 96 hours						
3. Test Dates:	September 04 - 08, 2009						
4. Test Temperature (°C):	22 <u>+</u> 1						
5. Light Quality:	Ambient Laboratory, 10-20 μE/m²/s						
6. Photoperiod:	16 h light, 8 h darkness						
7. Feeding Regime:	None						
8. Size of Test Vessel:	150 mL beaker						
9. Volume of Test Solutions:	120 mL						
10. No. of Test Organisms per Test Vessel:	5						
11. No. of Test Vessels per Treatment:	4						
12. Total No. of Test Organisms per Treatment:	20						
13. Test Concentrations (mg Cl/L):	8000, 4018, 2028, 1032, and 535						
Analytical Test Concentrations (geometric mean of samples collected at test initiation and termination-mg/L):	7750, 3899, 1900, 985 and 505						
15. Renewal of Test Solutions:	None						
16. Dilution and Primary Control Water:	EPA MHRW						
17. Test Material:	Sodium chloride: Sigma Aldrich, 99% pure ACS Reagent Cas. No. 7647-14-5, Lot # B0110043						
18. Secondary Control Water:	None						
19. Aeration:	None						
20. Endpoints Measured:	Mortality (LC <sub>50</sub> )

#### **Sulfate**

Table 107 provides a summary of estimated  $LC_{50}$  values for the two toxicity tests performed using sulfate.  $LC_{50}$  values ranged between 1,483 and 3,378 mg  $SO_4/L$ .

Table 107. LC<sub>50</sub> estimates for toxicity tests performed using sulfate.

<b>Test Species and Duration</b>	LC <sub>50</sub> (mg SO <sub>4</sub> /L)
Ligumia recta - 96 hr	1,483
Megalonaias nervosa - 96 hr	3,378

For each of the acute toxicity tests completed using sulfate, two tables were generated: the first summarizes the test results for each toxicity test, including nominal and analytical test concentration and  $LC_{50}$  estimates with confidence intervals; the second table summarizes analytical chemistry data collected throughout the toxicity tests.

### 96-hr Toxicity of Sulfate on Ligumia recta

The 96-hr test to determine the toxicity of sulfate on *L. recta* was completed by INHS. Test organisms, < 5-day old juveniles collected from the Missouri State University laboratory culture, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 5,000, 2,545, 1,317, 703, and 397 mg SO<sub>4</sub>/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 108; test results are provided in Table 109. Analytical chemistry data are provided in Table 110. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 32.

### 96-hr Toxicity of Sulfate on Megalonaias nervosa

The 96-hr test to determine the toxicity of sulfate on *M. nervosa* was completed by INHS. Test organisms, < 5-day old juveniles collected from the Genoa National Fish Hatchery, were acclimated to the dilution water (MHRW), test temperature and other test conditions prior to test initiation. Once acclimated, test organisms were examined for any disease, stress, parasites, etc. If free from ailments, test organisms were randomly assigned to the test chambers (which were randomly assigned to testing locations); four replicates were used per treatment with five organisms per replicate.

Organisms were exposed to a dilution water control and the test chemical at varying concentrations under static conditions. Serial dilutions of the highest test concentration (known weight of test chemical dissolved in a known volume of dilution water) were made to prepare the following nominal test concentrations: 5,000, 2,545, 1,317, 703, and 397 mg SO<sub>4</sub>/L.

Testing was conducted at  $20 \pm 1$  °C with a photoperiod of 16 hr light and 8 hr dark (ambient laboratory light). Organisms were not fed for the duration of the test and were examined daily for mortality. Once the test was complete, the LC<sub>50</sub> value was determined using the Spearman-Karber method.

A summary of the toxicity test conditions present throughout the assessment are provided in Table 111; test results are provided in Table 112. Analytical chemistry data are provided in Table 113. Accompanying information, including raw laboratory data, analytical chemistry data and statistical analyses, is provided in Appendix 33.
